Data Collection Periods for the Participating Institutions

Table S1

Data collection periods for the participating institutions

Institution	Academic term	Period
UBC	Term 1 (2024)	September 30, 2024 – December 6, 2024
	Term 2 (2025)	January 13, 2025 – April 7, 2025
	Term 1 (2025)	September 8, 2025 – November 26, 2025
	Term 2 (2026)	January 6, 2026 – March 28, 2026
UC Davis	Quarter Fall (2024)	Oct 13th to December 12th 2024
	Quarter Winter (2025)	February 2, 2025 – March 31, 2025
	Quarter Spring (2025)	April 2, 2025 – June 11, 2025
	Quarter Fall (2025)	September 28, 2025 – December 3, 2025
	Quarter Winter (2026)	January 21, 2026 – March 14, 2026
HU Berlin & U Siegen	Winter semester (2024/25)	November 7, 2024 – February 18, 2025
	Summer semester (2025)	April 14, 2025 – July 19, 2025
	Winter semester (2025/26)	October 13, 2025 – February 18, 2026

Note. UBC = University of British Columbia; UC Davis = University of California, Davis; HU Berlin = Humboldt-Universität zu Berlin; U Siegen = University of Siegen.

Deviations from the Pregistration

We deviated in several cases from the preregistered study design. Table S2 summarizes all deviations from the preregistered study design that affect study procedures or data collection. Changes affecting only the measured items (e.g., inclusion of additional items) are documented separately in the codebooks available on OSF. Table S1 displays the precise data collection periods at each institution. These periods also differ from the preregistration in (a) the exact dates (e.g., due to longer preparation times and site-specific timing of study initiation across institutions and academic terms) and (b) the number of academic terms included, as the data collection period was extended.

Table S2

Deviations from the preregistered study design affecting study procedures and data collection

Aspect of study design	Preregistered plan	Implemented change	justification	Date implemented
Participant recruitment	“Specifically, we target 300 participants each at UBC and UC Davis, and 200 participants combined for the German universities who meet these criteria. At UBC and UC Davis, we would ideally like to distribute the participants relatively equally across both terms (i.e., 150 participants per university per term). However, since we are unsure about the compliance rates in this extensive study, in all likelihood, we will instead target 300 participants per university in Term 1 to ensure that the target sample size can be reached even with a high drop-out rate. Due to the substantially smaller participant pool at the German universities, we will attempt to recruit as many participants as possible at any time during the data collection periods.”	Rather than strictly adhering to predefined recruitment targets per institution and term, we accepted as many eligible participants as possible at all participating institutions throughout the data collection period.	Data collection started later than planned, and recruitment proceeded more slowly than expected. Accepting as many eligible participants as possible increased the likelihood of reaching the desired final sample size within the available timeline.	October 2024 (start of data collection)
ESM exclusion criteria	“We will include three subsequent steps to remove participants that seem unlikely to meet this cut-off as early as possible from the study:	Participants were excluded earlier if their response rate fell below 50%, specifically starting on Day 4 in Condition A and Day 8 in Condition B.	Earlier exclusion ensured that participants had sufficient remaining time to improve their compliance and reach the required	November 1, 2024

	[...] Step 2: Participants who have a response rate of less than 50% at any day after the first half of the study has passed (i.e., after 7 days in Condition A and 14 days in Condition B).		number of completed surveys. When exclusion occurred later, participants often had insufficient time to recover their response rate. Participants who were excluded could request reinstatement if they indicated willingness to improve compliance, for example by adjusting notification settings or survey timing.	
Extension of ESM part	“In order to achieve the required number of reports, participants will thus have the option to extend the ESM part up to two (Condition A) or four (Condition B) days. With the usage of the additional days, an overall response rate of 77% would be sufficient to be invited for the follow-up. “	Participants were allowed to extend the ESM part by up to three additional days in Condition A and six additional days in Condition B.	This change increased the likelihood that motivated participants who had already demonstrated sufficient compliance could reach the required number of completed surveys.	November 21, 2024
ESM Notification method	From preregistration: “Invitations and reminders for the surveys will be sent via (a) text message only, (b) email only, or a (c) combination of both, depending on the participant’s preference. If participants select option (b), they will not receive reminders due to restrictions on the number of emails that can be sent per day by the study's platform. In addition, participants at	We removed the option of receiving notifications via text message only that had initially been offered to the North American samples. In the initial combined option, participants first received the invitation via text message and then the reminder via email. We added an additional	The removal of the text message only option was implemented to reduce costs. Adding the additional combined option allowed participants to choose their preferred order of notifications and additionally helped reduce	January 1, 2025

	German institutions were not offered option a due to the substantial higher costs for text messages in Germany compared to North America.”	combined option that allowed participants to first receive the invitation via email and then the reminder via text message. We also changed the email-only option such that participants could receive both invitations and reminders via email.	costs when participants selected email as the primary notification method. The change to the email-only option was possible because we were able to increase the number of emails that could be sent by the study platform.	
Data collection period	“The data collection period will span from September 2024 to July 2025 [...]”	The data collection period was extended until March 2026.	Recruitment proceeded more slowly than expected, and only approximately half of the planned sample had completed the study by the original end date. Extending the data collection period allowed recruitment of the remaining participants.	July 31, 2025
Information on timing ESM surveys	The preregistration did not explicitly specify whether participants would receive information about the timing of upcoming surveys. However, in the planned study setup, participants received a general message after completing an ESM survey stating that they would receive the next survey within a few hours.	For approximately two-thirds of participants (randomly selected), this message was modified to provide more specific information about the timing of the next survey within a study day. Specifically, participants were informed that the earliest possible time of the next survey would be one hour later in Condition A and two hours later in Condition B.	This change was introduced as an experimental manipulation to examine whether providing more specific information about survey timing influences participant compliance.	September 7, 2025

Selection of Personality State Items

The assessment of momentary expressions of personality (i.e., personality states) in daily life is a central approach to studying personality dynamics. Personality states are commonly assessed using trait adjectives with instructions to rate how much the adjective applies at the moment. Despite their widespread use, assessment practices vary widely across studies, and only few instruments have been systematically validated for the measurement of personality states (Horstmann & Ziegler, 2020). A notable recent development is the Five-Factor Model Personality States Inventory (FFMPSI; Gander et al., 2025), which has so far been validated for the German language.

However, we did not use the FFMPSI because it employs a bipolar item format. Bipolar items assume that the two adjectives represent mutually exclusive and symmetric poles of a single underlying continuum. For some descriptors, this assumption may be difficult to justify, as the two poles may not be strict opposites and may not be mutually exclusive. Accordingly, responses to such items can be ambiguous with respect to which construct is primarily being assessed. For example, a person may feel neither balanced nor irritable: their lack of balance may stem from poor sleep or a sad message, without this making them irritable to the same degree. Likewise, a person may feel sociable (wanting to be around others) while still being shy (nervous in direct interactions). If the focus of responding varies over time within individuals, this ambiguity could complicate the interpretation of within-person dynamics and, in principle, resemble attractor-like patterns that arise from measurement rather than from the underlying dynamics of the state itself. To minimize such interpretational ambiguity, we chose unipolar items for the PACE Study.

In addition, recent work suggests that some commonly used personality state items may not be well applicable to participants' daily lives (Kritzler et al., 2023a). Consistent with this, cognitive interviews conducted as part of the larger research project revealed that

participants were sometimes unsure about the meaning of commonly used state adjectives, even though these items were not the primary focus of the interviews. Together, these considerations motivated a pretest to empirically evaluate and select personality state items that are both interpretable and suitable for capturing personality dynamics in daily life.

For the PACE Study, we selected the 15 personality state measures based on the following criteria. First, the items should represent all facets of the BFI-2 (Soto & John, 2017) to ensure a broad assessment of the personality space. Second, the item should have the same meaning and connotation in English and German. Third, the items should be easily understood by participants. Fourth, the items should demonstrate convergent and discriminant validity, whereby convergent validity was valued higher than discriminant. Fifth, ideally there should be one item per dimension that is reverse-keyed (i.e., phrased in a less socially desirable direction) to reduce acquiescence bias and ensure coverage of the full range of each dimension. Sixth, the items should display intraindividual variation for a large percentage of individuals. Seventh, the items should be applicable to a wide range of situations in the daily life of students. Using these criteria, we first selected 28 items that were either part of the FFMPSI or were identified as most promising in a literature search. These 28 items were then empirically compared in a pretest ($N = 297$) with undergraduates from the University of British Columbia. Based on the results of the pretest, all final 15 selected items appear to meet at least criteria 1-4. More details are described in the following sections.

Method

This pretest was approved by the ethics review board of the University of British Columbia (H24-01767). Data were collected online in summer 2024 using formr . In addition to the personality state items described below, the study included a first test of a personalization procedure for situational items in ESM studies; results of that procedure are reported elsewhere. In total, 207 participants completed the personality state item section.

For the purpose of the item selection, the following questions were included:

1. *Situational ratings*: Participants were asked to think about their situation approximately one hour before they started filling out the survey. To facilitate recall, they briefly described where they were, what they were doing, and who they were with. They were then asked to respond to the personality state items as if they were still in that situation. Although each participant provided only a single response per item, which does not permit a decomposition of between- and within-person variance, the situation-specific framing of the instruction was intended to elicit state-level responses rather than general self-descriptions. Because participants recalled situations from their own daily lives, suitable state items were expected to show dispersion across respondents rather than clustering at a single response category. Such dispersion indicates that the items vary across the types of situations participants actually experience.
2. *Suitability ratings*: Participants were asked to think about a typical week and describe the places they go to, the activities they engage in, and the people they are with. They then rated the relevance of each item as a descriptor of their thoughts, feelings, and behaviors during a typical week. Participants were instructed that if an item was relevant only in situations they rarely experience, they should assign a lower rating than to items relevant in more frequently occurring situations.
3. *Uncertainty selection*: Participants were asked to indicate all items for which they experienced difficulties responding due to uncertainty about the meaning of the item.

Selection of initial item pool for the pretest

To operationalize the selection criteria described above, we additionally defined exclusion criteria that guided the construction of the initial item pool for the pretest.

Specifically, we excluded:

- Negatively worded items (e.g., unrestrained, unadventurous), as these would introduce double negation when combined with the lower end of the response scale (e.g., “not at all”), thereby complicating response interpretation.
- Items whose meaning was not known to at least one participant in the cognitive interviews conducted with approximately 30 undergraduates (e.g., unsophisticated).
- Items with potentially ambiguous meanings without further clarification. For example, one participant asked in the cognitive interviews whether careless referred to the completion of tasks and duties (conscientiousness) or to the degree of concern about others’ opinions (neuroticism). Similar ambiguities applied to items such as attentive, patient, or calm, where differing interpretations could shift the primary dimension being assessed.
- Items expected to show strongly skewed distributions in a student sample (e.g., choleric, hostile). When semantically similar items were available, we selected those presumed to be less extreme (e.g., blue instead of depressed).

Items that describe dynamic patterns rather than momentary states and thus overlap with the target constructs of the present analyses (e.g., moody).

For the pretest, we selected six items per personality dimension, except for openness, for which only four suitable items were identified. We did not include multiple items for all facets, as for some facets we were already relatively confident that the selected item would perform well (e.g., sociable for sociability), allowing us to allocate more items to facets for which selection was less straightforward. In one other case, specifically for the respectfulness facet of agreeableness, we included only one item (*polite*) as the negatively-pooled version that seemed most suitable (*rude*) would have introduced a double-negation in the German version (*unhöflich*). An overview of all items included in the pretest is provided below.

Table S3

Item pool of the pretest to select the personality state items

Dimension	Facet	Item English	Item German	Pooling
neuroticism	anxiety	nervous	nervös	positive
neuroticism	anxiety	relaxed	entspannt	negative
neuroticism	depression	carefree	sorgenfrei	negative
neuroticism	depression	blue	niedergeschlagen	positive
neuroticism	emotional volatility	irritable	gereizt	positive
neuroticism	emotional volatility	balanced	ausgeglichen	negative
extraversion	sociability	sociable	gesellig	positive
extraversion	assertiveness	assertive	durchsetzungsfähig	positive
extraversion	assertiveness	subordinate	unterordnend	negative
extraversion	energy	active	aktiv	positive
extraversion	energy	passive	passiv	negative
extraversion	energy	enthusiastic	enthusiastisch	positive
agreeableness	compassion	sympathetic	verständnisvoll	positive
agreeableness	compassion	aloof	abweisend	negative
agreeableness	compassion	kind	freundlich	positive
agreeableness	respectfulness	polite	höflich	positive
agreeableness	trust	suspicious	misstrauisch	negative
agreeableness	trust	trustful	vertrauenswürdig	positive
conscientiousness	organization	organized	organisiert	positive
conscientiousness	organization	tidy	ordentlich	positive
conscientiousness	productiveness	lazy	faul	negative
conscientiousness	productiveness	diligent	fleißig	positive
conscientiousness	responsibility	thoughtless	gedankenlos	negative
conscientiousness	responsibility	reliable	zuverlässig	positive
openness	aesthetic sensitivity	artistic	künstlerisch	positive
openness	intellectual curiosity	curious	neugierig	positive
openness	creative imagination	conventional	konventionell	negative
openness	creative imagination	traditional	traditionell	negative

Results: Distribution of Situational Ratings

Participants were instructed to think about a situation about one hour before completing the survey and to respond to the personality state items as if they were still in that situation.

For neuroticism, all positively scored items were strongly skewed (see Figure S1). Among the negatively scored items (i.e., items ending in “_r”), *balanced* showed a comparatively more even distribution.

Figure S1

Distribution of Situational Ratings for Neuroticism Items

Note. r = reverse-scored item.

For extraversion, items within the same facet either showed similar distributions (energy) or differed in ways that were not immediately clear (see Figure S2). For assertiveness, both items were right-skewed, but *subordinate* showed a comparatively higher frequency in the middle response category.

Figure S2

Distribution of Situational Ratings for Extraversion Items

Note. r = reverse-scored item.

For agreeableness, for the two facets for which both positively and negatively scored items were included (compassion and trust), the positively scored items showed comparatively more even distributions (see Figure S3). Among the negatively scored items for these facets, *aloof* showed a more even distribution than *suspicious*. For respectfulness, the two items showed similar distributions.

Figure S3

Distribution of Situational Ratings for Agreeableness Items

Note. r = reverse-scored item.

For conscientiousness, for the facets for which both positively and negatively scored items were included (reliability and organization), the positively scored items again showed comparatively more even distributions (see Figure S4). Among the negatively scored items, *lazy* showed a more even distribution than the *thoughtless*. For organization, the two items showed similar distributions.

For openness, *conventional* showed a slightly more even distribution than *traditional* (see Figure S5).

Figure S4

Distribution of Situational Ratings for Conscientiousness Items

Note. r = reverse-scored item.

Figure S5

Distribution of Situational Ratings for Conscientiousness Items

Note. r = reverse-scored item.

Results: Correlations Among Personality State Items Under Situational Instructions

To evaluate the construct validity of the candidate items, we examined correlations among the personality state ratings obtained under the situational instruction (see Figure S6). Because each participant provided a single state rating per item based on a recalled situation, these correlations reflect cross-sectional covariation across individuals recalling different everyday situations rather than within-person covariation over time. Ideally, items should show strong correlations with other items from the same personality dimension (convergent validity) and comparatively weaker correlations with items from other dimensions (discriminant validity). Overall, the results suggested that limitations in discriminant validity were more pronounced than limitations in convergent validity.

Figure S6

Correlations Among Personality State Items Under Situational Instructions

Note. r = reverse-scored item.

For neuroticism, *balanced* showed comparatively strong correlations with items from other dimensions (e.g., *enthusiastic*, *kind*), suggesting rather low discriminant validity. The other neuroticism items showed more differentiated patterns, although several items correlated substantially with *suspicious*, and *nervous* additionally showed elevated correlations with *subordinate*.

For extraversion, the items showed a relatively large number of substantial correlations with items from other dimensions, with the exception of neuroticism. This pattern was particularly pronounced for *sociable*. Within the assertiveness facet, the two items showed similar patterns. Within the energy facet, *passive* showed low convergent validity, whereas *active* and *enthusiastic* demonstrated relatively low discriminant validity. Particularly *enthusiastic* showed relatively strong correlations with several agreeableness items (e.g., *kind*, *polite*).

For agreeableness, several items showed notable correlations with items from other dimensions. An exception was *aloof* (compassion facet), which showed comparatively better discriminant validity. For respectfulness, the two items showed similar correlation patterns. Within the trust facet, *suspicious* showed strong correlations with neuroticism items, whereas *trustful* showed stronger correlations with items from other dimensions.

For conscientiousness, *thoughtless* showed a notably low convergent validity with the other conscientiousness items, which suggests that *reliable* should be selected for the responsibility facet. However, it should also be noted that *reliable* showed strong correlations with extraversion and agreeableness items. Within the productiveness facet, *lazy* showed comparatively better discriminant validity than *diligent*. For organization, the two items showed similar patterns.

For openness, *traditional* and *conventional* showed largely comparable correlation patterns, with no clear advantage of one item over the other.

Results: Distribution of Suitability Ratings

Participants were asked to rate how relevant they think each personality state item is as a descriptor of their thoughts, feelings, and behaviors during a typical week. Through this item format, we aimed to gauge whether there are substantial differences in how suitable participants perceive the items to be in their everyday life. When interpreting the results, it is important to keep in mind that this was a novel item format, and it is unclear how well it functioned as intended. Thus, the results should be interpreted with caution.

For neuroticism, there were no clear differences between items, except for *blue*, for which about 40% of participants indicated that this item would not at all be relevant during a typical week (see Figure S7).

Figure S7

Distribution of Suitability Ratings for Neuroticism Items

Note. r = reverse-scored item.

For extraversion, the negatively scored items (*passive*, *subordinate*) were perceived as slightly less suitable, but there were no substantial differences between these items (see Figure S8).

Figure S8

Distribution of Suitability Ratings for Extraversion Items

Note. r = reverse-scored item.

For agreeableness, both negatively scored items were rated as substantially less suitable than the positively scored items, with *suspicious* displaying more extreme ratings than *aloof* (e.g., about 80% indicated that *suspicious* is not at all relevant during a typical week; see Figure S9).

For conscientiousness, the differences between items were rather small, but *thoughtless* was rated as least suitable, whereas *reliable* was rated as particularly suitable. For openness, there were no substantial differences between the items (see Figure S10).

Figure S9

Distribution of Suitability Ratings for Agreeableness Items

Note. r = reverse-scored item.

Figure S10

Distribution of Suitability Ratings for Conscientiousness Items

Note. r = reverse-scored item.

For openness, there were no substantial differences between the items (see Figure S11).

Figure S11

Distribution of Suitability Ratings for Openness Items

Note. r = reverse-scored item.

Results: Identification of Unclear Items

Lastly, participants were instructed to select all adjectives whose meaning they were unsure about. The results are displayed in Figure S12.

The items most frequently identified as unclear were *aloof*, *subordinate*, *conventional*, and *traditional*.

Figure S12

Proportion of Participants Who Found the Item Unclear

Note. r = reverse-scored item.

Integration of Results and Final Decision on Item Selection

For neuroticism, all positively-scored (less socially desirable) items were strongly skewed, which could cause issues in the analysis of the ESM data. However, we still selected *irritable* given that the other item for the emotional volatility facet (*balanced*) demonstrated low convergent and discriminant validity. For the other two facets, we selected the negatively-scored items (*relaxed*, *carefree*), which showed more favorable distributional characteristics.

For extraversion, we only included multiple items for two facets (assertiveness and energy). For assertiveness, we decided against using *subordinate* given that a large percentage of participants was unsure about the meaning of this item, which meant that we had to take *assertive* instead. For the energy facet, we decided against *passive* as it demonstrated low convergent validity with the other extraversion items, and preferred *active* over *enthusiastic* due to slightly better – but still not ideal – discriminant validity. Note that

this decision implied that we failed to achieve our aim to select at least one item that is phrased in a less socially desirable direction (i.e., negatively scored for extraversion) in order to achieve our higher prioritized aims (e.g., understandability and convergent validity).

For agreeableness, we again only included multiple items for two facets. For the compassion facet, a substantial proportion of participants indicated that they were unsure about the meaning of *aloof*, which is why we decided against including this item. *Kind* and *sympathetic* performed very similarly in the pretest, but we ultimately chose *kind* as it had a particularly high suitability rating, despite its low discriminant validity. For the trust facet, *suspicious* demonstrated insufficient convergent and discriminant validity, and was additionally rated as rather unsuited to describe the students' experiences and behaviors in a typical week. Thus, we chose *trustful* instead, despite its low discriminant validity.

For conscientiousness, there were no substantial differences between both items for the organization facet, so we chose *organized* as we expected it to be somewhat broader than *tidy*. For the productiveness facet, *lazy* demonstrated slightly better discriminant validity than *diligent*, and *diligent* was unclear to about 8% of the participants, which is why we chose *lazy*. For the responsibility facet, *thoughtless* showed low convergent validity with the other conscientiousness items, and was also rated as rather unsuited to describe the students' experiences and behaviors in a typical week. Thus, we decided to take *reliable* instead, despite its low discriminant validity.

For openness, we only included four items in the pretest, as it was very difficult to find items that seemed promising in both English and German. This meant that only for the creative imagination facet were we able to make a decision based on the pretest results. However, both items for this facet, *conventional* and *traditional*, were frequently identified as unclear in their meaning and demonstrated relatively low convergent and discriminant validity. Thus, we decided against including either of these two items and instead chose

creative. *Creative* was not included in the pretest since we expected it to be very similar to the other items (*artistic, curious*). However, especially after seeing the very poor performance of the other two items, we decided that it would be preferable to include three relatively similar items for openness rather than including an item that may not be well understood by a large proportion of participants.

Descriptive Statistics of the Key Constructs Assessed in the ESM Part

Table S4

Descriptive Statistics of the Key Construcs Assessed in the ESM Part

Construct	Item	Mean	Range	Between-person SD	Mean within-person SD	Range within-person SD
Situation Characteristics	duty	5.49	1-10	1.54	2.52	0-6.36
	sociality	5.01	1-10	1.38	2.76	0-6.36
	negativity	3.36	1-10	1.41	1.89	0-4.95

	stressed	4.94	1-10	1.48	1.87	0-4.24
Biological States	tired	5.43	1-10	1.49	1.88	0-4.24
	hungry	4.07	1-10	1.38	2.12	0-4.95

Note. Estimates are based on 1907 participants who provided in total 130,402 complete ESM surveys.

Visualization of Interfaces of Selected Item Formats

Figure S13 displays the interface through which participants could modify the values selected as their attractors based on the modes estimated from their responses to the PERDI. Figures S14 and S15 display the interface of the items assessing participants' social network.

Figure S13

Interface used by participants to modify the initially selected typical value(s) (i.e., attractors) based on their PERDI responses

Sociability: not at all sociable to extremely sociable

Based on your responses, for your typical way(s) of being **sociable**, we would have chosen the following value(s): **2, 6**

Does this align with your perception or would you like to make any changes?

☐ This selection aligns with my perception. ☒ I would like to make changes to this selection.

How many different values are needed to describe your typical way(s) of being **sociable** in your perception?

2 different values are needed

Please insert the values for your typical way(s) of beings below (one value per box)

Value 1: 2

Value 2: 7

Just as a reminder, here are the responses you provided regarding your current level of sociability (please do *not* modify):

1: 10	2: 30	3: 10	4:	5: 15
6: 20	7: 15	8:	9:	10:

Note. Participants were first shown the value(s) that were estimated as their typical way(s) of being based on the modes of their PERDI responses. If participants indicated that they would like to make changes, they first selected how many typical ways of being (i.e., attractors) best described their experience (between 1 and 4 values), and could then modify the precise location of these values. In this example, the participant retained the number of attractors but slightly adjusted the location of the second attractor (from 6 to 7).

Figure S14

Interface used to assess the size and composition of participants' social network

How many people do you know?

Please count how many people you know in each of the categories listed below. If you cannot immediately provide an exact number, please estimate. Please count each person only once: If specific people fit into multiple categories (e.g., a colleague you are friends with), place them only in the most fitting category.

Please distinguish between people who are "very close" or "somewhat close" to you.

- **"Very close people"**: These are people you talk with about important matters, you are regular in contact with or who are there for you if you need help
- **"Somewhat close people"**: These are people who are more than casual acquaintances but are not very close.

Please now indicate how many people you know from the following categories.

If you cannot think of anyone to put in a particular category, please enter 0.

Contact	Very close	Somewhat close
Parents	2	0
Siblings	2	1
Children	1	0
Extended family	0	2
Romantic partners	1	0
Friends	3	3
Rommates/neighbours	0	5
Classmates	2	5
Co-workers	0	3
Hobbies/volunteering		3
Other people	0	0

S15

Interface used to assess the frequency of in-person contact with participants' very close social network members

Very Close Contacts: Frequency of In-Person Contact

In this part of the survey, we are interested in how often you have regular **in-person contact** with "very close" people. Please assign all very close people from each category (e.g., parents, siblings) to one of the following three frequency groups:

- a) Meet in person at least once a week
- b) Meet in person at least once a month (but less than once a week)
- c) Meet in person less than once a month

Notes:

- The sum of the numbers in the frequency groups for each category (e.g., siblings) must equal the total number of very close people in that category, as displayed in the **Number** column. Each individual can only be assigned to one frequency group.
- Please do *not* modify the values in the Number column.

Example:

If you have 3 very close siblings and indicate that you:

- a) Meet 2 siblings at least once a week in person
- b) Meet 0 siblings at least once a month in person
- c) Meet 1 sibling less than once a month in person

then the sum of the frequency groups is 3 (2+0+1 = 3), which matches the total number of your very close siblings.

In-person contact	Number <i>please don't modify</i>	At least once a week	At least once a month	Less than once a month
Parents	2			
Siblings	2
